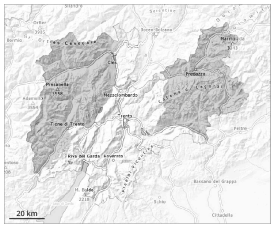
Danger Level 2 - Moderate



Tendency: Constant avalanche danger
on Thursday 23 04 2026

Wet snow

Persistent
weak layer

Increase in danger of wet avalanches in the course of the day.

As a consequence of warming during the day and solar radiation there will be an increase in the danger of wet avalanches.
From origins in starting zones where no previous releases have taken place natural avalanches are possible, even medium-sized ones. This applies on shady slopes below approximately 2700 m, as well as on sunny slopes at elevated altitudes. On steep shady slopes avalanches can be released in the weakly bonded old snow and reach large size in isolated cases.
Individual avalanche prone locations for dry avalanches are to be found on very steep shady slopes above approximately 2500 m. Such avalanche prone locations are difficult to recognise.

Snowpack

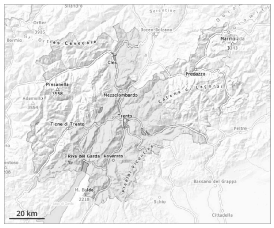
Danger patterns dp.10: springtime scenario dp.1: deep persistent weak layer

Some snow will fall in some regions. The surface of the snowpack will soften during the day. Sunshine and high temperatures will give rise to increasing and thorough wetting of the snowpack below approximately 2700 m.
Steep west, north and east facing slopes above approximately 2400 m: Faceted weak layers exist in the bottom section of the old snowpack.
Below approximately 1800 m from a snow sport perspective, in most cases insufficient snow is lying.

Tendency

Thursday: The avalanche danger will persist.

Danger Level 1 - Low



1

Tendency: Constant avalanche danger
on Thursday 23 04 2026

Wet snow requires caution.

Only isolated wet avalanches are possible. Caution is to be exercised on extremely steep shady slopes. Mostly avalanches are rather small.

Below approximately 2000 m from a snow sport perspective, in most cases insufficient snow is lying.

Snowpack

Danger patterns dp.10: springtime scenario

The surface of the snowpack will soften during the day.

Tendency

Thursday: The avalanche danger will persist.
