Danger Level 2 - Moderate

2800m

Tendency: Constant avalanche danger
on Tuesday 28 04 2026

Wet snow

2800m

Persistent
weak layer

2500m

The danger of wet avalanches will already be elevated in the early morning.

From the early morning as a consequence of warming during the day and solar radiation there will be an increase in the danger of wet avalanches. Wet avalanches can in isolated cases be released by a single winter sport participant. This applies on very steep shady slopes below approximately 2800 m, as well as on very steep sunny slopes at elevated altitudes.

Individual avalanche prone locations for dry avalanches are to be found on very steep shady slopes above approximately 2500 m. Especially transitions from a shallow to a deep snowpack are unfavourable. The avalanche prone locations are difficult to recognise.

Snowpack

Danger patterns dp.10: springtime scenario | dp.1: deep persistent weak layer

The surface of the snowpack will freeze to form a strong crust only at high altitudes and will soften quickly. Sunshine and high temperatures will give rise to rapid moistening of the snowpack at intermediate and high altitudes.

Shady slopes above approximately 2500 m: Faceted weak layers exist in the bottom section of the old snowpack at elevated altitudes.

In particular in the Prealps as well as below approximately 1800 m hardly any snow is lying. Little snow will fall in some localities.

Tendency

Outgoing longwave radiation during the night will be reduced. The danger of wet avalanches will already be elevated in the early morning. In some localities 5 to 15 cm of snow will fall above approximately 2500 m.
