Danger Level 3 - Considerable

Tendency: Constant avalanche danger
on Thursday 05 03 2026

Persistent
weak layer

2000m

Weakly bonded old snow represents the main danger.

Avalanches can be released in the old snowpack and reach large size. This applies even in case of a single winter sport participant. The avalanche prone locations are to be found especially on west, north and east facing slopes above approximately 2000 m and in all aspects at elevated altitudes. Caution is to be exercised in particular at transitions from a shallow to a deep snowpack. Whumpfing sounds can indicate the danger. Remotely triggered avalanches are possible.

As a consequence of warming during the day and solar radiation only isolated mostly small wet avalanches are possible below approximately 2200 m. Many starting zones have released the snow.

Snowpack

Danger patterns dp.1: deep persistent weak layer | dp.10: springtime scenario

Shady slopes: Distinct weak layers exist in the old snowpack in particular on west, north and east facing slopes.

Outgoing longwave radiation during the night will be good. The surface of the snowpack will freeze to form a strong crust. The weather conditions as the day progresses will give rise to softening of the snowpack in particular on very steep sunny slopes.

Tendency

Weakly bonded old snow requires caution. Single winter sport participants can release avalanches as before.

Increase in danger of wet avalanches as a consequence of warming during the day and solar radiation.

Danger Level 2 - Moderate

Tendency: Constant avalanche danger
on Thursday 05 03 2026

Persistent weak layer

2000m

Weakly bonded old snow requires caution.

Avalanches can in some cases be released in the old snowpack and reach quite a large size on west, north and east facing slopes. This applies even in case of a single winter sport participant in some cases. The avalanche prone locations are to be found in particular above approximately 2000 m. Caution is to be exercised in particular at transitions from a shallow to a deep snowpack, when entering gullies and bowls for example.

Only isolated mostly small wet avalanches are possible below approximately 2200 m. Many starting zones have released the snow.

Snowpack

Danger patterns dp.1: deep persistent weak layer | dp.10: springtime scenario

Shady slopes: Distinct weak layers exist in the old snowpack in particular on west, north and east facing slopes. This applies especially above approximately 2000 m.

Outgoing longwave radiation during the night will be good. The surface of the snowpack will freeze to form a strong crust. The weather conditions as the day progresses will give rise to softening of the snowpack in particular on very steep sunny slopes.

Tendency

Weakly bonded old snow requires caution. Slight increase in danger of wet avalanches as a consequence of warming during the day and solar radiation.

Danger Level 2 - Moderate

Tendency: Constant avalanche danger
on Thursday 05 03 2026

Persistent
weak layer

Treeline

Weak layers in the old snowpack can still be released in isolated cases.

Avalanches can in isolated cases be released in the old snowpack and reach medium size in isolated cases on northwest, north and northeast facing slopes. This applies in case of a single winter sport participant. In their paths avalanches can entrain the wet snow.

As a consequence of warming during the day individual wet avalanches are possible.

Snowpack

Danger patterns dp.1: deep persistent weak layer | dp.10: springtime scenario

Shady slopes: Distinct weak layers exist in the old snowpack in particular on west, north and east facing slopes.

The weather conditions gave rise to moistening of the snowpack below approximately 1800 m.

Tendency

Weakly bonded old snow requires caution. Slight increase in danger of wet avalanches as a consequence of warming during the day and solar radiation.
