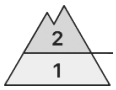
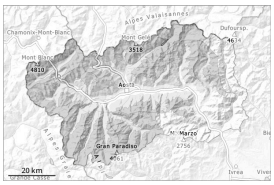
PM:



2200m

Tendency: Constant avalanche danger
on Saturday 18 04 2026



Wet snow

3200m
2200m

Wind slab

3000m

The danger of moist and wet avalanches will increase quickly during the day.

The conditions are generally favourable for ski touring.
The surface of the snowpack will freeze to form a strong crust and will soften quickly.
In the late morning the natural activity of moist and wet avalanches will gradually increase. In starting zones where no previous releases have taken place and on very steep slopes more small and, in isolated cases, medium-sized moist snow slides and avalanches are possible.
Backcountry tours and ascents to alpine cabins should be concluded timely.
As a consequence of new snow and a sometimes moderate southeasterly wind, mostly small wind slabs formed on Monday. They have formed at high altitudes and in high Alpine regions.

Snowpack

Danger patterns dp.10: springtime scenario

The surface of the snowpack has frozen to form a strong crust. New snow and wind slabs are lying on a wet old snowpack.
At higher altitudes, snow cover becomes thinner and patchy; it is better at mid-altitudes, which are less exposed to the wind. Below approximately 1900 m hardly any snow is lying.
Weak layers exist in the snowpack in particular on steep shady slopes.

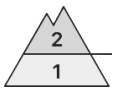
As a consequence of the snow drift accumulations will stabilise during the next few days.

Tendency

As a consequence of warming during the day and solar radiation more moist and wet avalanches are possible. Sunshine and high temperatures will give rise to settling of the snowpack.

Danger Level 2 - Moderate

AM:



3000m

Tendency: Constant avalanche danger
on Saturday 18 04 2026

Wet snow

3200m
2200m

Wind slab

3000m

The danger of moist and wet avalanches will already be elevated in the early morning. In the event of an overcast night this applies.

Early morning: The conditions are generally favourable for ski touring.
If there is cloud cover at night combined with warm air, the avalanche risk will already be 2 (moderate) by the morning because The surface of the snowpack will only just freeze.
In the late morning the natural activity of moist and wet avalanches will quickly increase. In particular in starting zones where no previous releases have taken place and on very steep slopes more medium-sized and, in isolated cases, large natural wet avalanches are to be expected.
Backcountry tours and ascents to alpine cabins should be concluded timely.
As a consequence of new snow and a sometimes moderate southeasterly wind, sometimes avalanche prone wind slabs formed on Monday. They have formed at high altitudes and in high Alpine regions.

Snowpack

Danger patterns dp.10: springtime scenario

20 to 40 cm of snow, and even more in some localities, fell on Monday above approximately 2300 m. The weather conditions gave rise to rapid settling of the snowpack. New snow and wind slabs are lying on a wet old snowpack.

At higher altitudes, snow cover becomes thinner and patchy; it is better at mid-altitudes, which are less exposed to the wind. Below approximately 1900 m hardly any snow is lying.
Weak layers exist in the snowpack in particular on steep shady slopes.
As a consequence of the snow drift accumulations will stabilise during the next few days.

Tendency

The spring-like weather conditions will give rise to settling of the snowpack. As the moisture increases more moist and wet avalanches are possible.
