

Avalanche danger

updated on 8.6.2025, 17:00

region A

Moderate (2=)

Wind slab

Avalanche prone locations

Danger description

Fresh and older wind slabs are to be found in particular adjacent to ridgelines and in gullies and bowls. They can in some places be released by a single winter sport participant and reach medium size. The wind slabs are to be evaluated with care and prudence in particular in very steep terrain. Apart from the danger of being buried, restraint should be exercised as well in view of the danger of avalanches sweeping people along and giving rise to falls.

The Avalanche Warning Service currently has only a small amount of information that has been collected in the field, so that the avalanche danger should be investigated especially thoroughly in the relevant locality.

Moderate (2)

Wet snow

As a consequence of warming during the day and solar radiation wet avalanches are to be expected as the day progresses, even medium-sized ones. Caution is to be exercised in particular on very steep slopes in high Alpine regions. Backcountry tours should be started early and concluded timely.

region B

Low (1)

Wet snow

As a consequence of warming during the day and solar radiation wet avalanches are possible as the day progresses. This applies in particular on very steep north facing slopes at elevated altitudes. Backcountry tours should be concluded timely. The Avalanche Warning Service currently has only a small amount of information that has been collected in the field, so that the avalanche danger should be investigated especially thoroughly in the relevant locality.

Avalanche bulletin through Monday, 9. June 2025**Snowpack and weather**

updated on 8.6.2025, 17:00

Snowpack

Below approximately 3000 m, the snowpack is saturated by the rain. In the high Alpine regions, snow fell on repeated occasions at the end of the week, most of it in the Bernina region, where around 1m accumulated. The fresh snow was transported by the sometimes strong southwesterly to westerly wind.

Weather review of Whit Sunday

The precipitation from the west ended during the night. During the day, it remained mostly cloudy on the central and eastern parts of the northern flank of the Alps and in northern Grisons, while elsewhere it became increasingly sunny.

Fresh snow

The snowfall level was 2900 m in the northwest and 3200 m in the southeast. From Friday afternoon to Sunday morning, the following amounts fell in the high Alpine regions:

- Northern Alpine Ridge from the Trient to the Bernese Oberland, Rheiwaldhorn, Val Bregaglia: 15 to 30 cm
- Less elsewhere

Due to the showery precipitation, the exact amounts vary from place to place.

Temperature

At midday at 2000 m, between +5 °C in the north and +11 °C in the south

Wind

Sometimes strong from the west in the high Alpine regions

Weather forecast until Whit Monday

During the first half of the night, it will still be partly cloudy in the northeast. Otherwise, the night will be clear and the day mostly sunny.

Fresh snow

-

Temperature

At midday, the zero-degree level will be 3800 m

Wind

There will be a westerly wind:

- Still strong to stormy in the high Alpine regions at the beginning of the night
- Light to moderate during the day.

Outlook until Wednesday

After mostly clear nights, it will be mostly sunny during the day. The zero-degree level will rise to 4200 m and there will be a light to moderate westerly wind in the high Alpine regions.

The danger of dry avalanches will decrease further and continue to mainly affect extremely steep northern slopes above approximately 3400 m. Elsewhere, generally favourable conditions will prevail in the early morning. Due to the warmer temperatures and solar radiation, wet avalanches are possible during the day. Ski touring should be started early and finished in good time.
