

Avalanche danger

updated on 7.7.2025, 17:00

region A

Considerable (3-)

New snow

Avalanche prone locations

Danger description

40 to 60 cm of snow will fall until the evening above approximately 2800 m. The fresh snow and the wind slabs that are being formed by the moderate northwesterly wind are prone to triggering. Persons can release avalanches, including medium-sized ones. Individual natural avalanches are possible. Backcountry touring calls for experience in the assessment of avalanche danger. Apart from the danger of being buried, restraint should be exercised as well in view of the danger of avalanches sweeping people along and giving rise to falls.

Danger levels

region B

Moderate (2=)

New snow

Avalanche prone locations

Danger description

20 to 40 cm of snow will fall until the evening above approximately 2800 m. The fresh snow and the mostly small wind slabs that are being formed by the moderate northwesterly wind are in some cases prone to triggering. Persons can release avalanches. Even a small avalanche can sweep people along and give rise to falls. Meticulous route selection is recommended.

region C

Low (1)

New snow

Avalanche prone locations

Danger description

10 to 20 cm of snow will fall until the evening above approximately 2800 m. Avalanches can in isolated cases be released by people, but they will be small in most cases. Even a small avalanche can sweep people along and give rise to falls. Meticulous route selection is recommended.

## Snowpack and weather

updated on 7.7.2025, 17:00

### Snowpack

A mostly continuous snow cover was found only on north-facing slopes and glaciers above approximately 3000 /m. In recent weeks, the snowpack has become wet up to the highest elevations. No weak layers are currently known.

### Outlook

Showers are still possible in the east on Wednesday morning. Otherwise, Wednesday and Thursday will be mostly sunny. The zero-degree level will rise to 3800 /m in the west and 3000 /m in the east until Thursday. Especially on Wednesday, wet-snow avalanches are possible in high alpine terrain due to solar radiation and warming. In isolated cases, they may entrain the wet snowpack and become large. The danger of dry avalanches is decreasing.
