

AM

PM

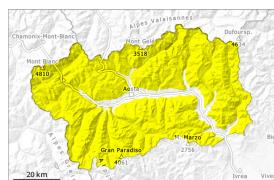

Danger Level 2 - Moderate

Tendency: Constant avalanche danger

on Tuesday 06 05 2025

Wet snow

Snowpack stability: **very poor**

Frequency: **few**

Avalanche size: **medium**

New snow

Snowpack stability: **very poor**

Frequency: **some**

Avalanche size: **small**

The weather conditions gave rise to rapid and thorough wetting of the snowpack over a wide area.

The snowpack will become prone to triggering also on shady slopes.

In particular in starting zones where no previous releases have taken place small and medium-sized moist and wet avalanches are to be expected. Occasionally large natural avalanches are possible in isolated cases, caution is to be exercised in particular on very steep north, northeast and northwest facing slopes below approximately 2800 m, and on very steep sunny slopes.

The new snow and wind slabs are in some cases prone to triggering in all aspects above approximately 2800 m. In addition as the day progresses especially at high altitudes and in high Alpine regions, some mostly small dry avalanches are possible.

The Avalanche Warning Service currently has only a small amount of information that has been collected in the field, so that the avalanche danger should be investigated especially thoroughly in the relevant locality.

Snowpack

Danger patterns

dp.10: springtime scenario

Over a wide area a mostly overcast night: The surface of the snowpack will only just freeze and will already be soft in the early morning.

Above approximately 2900 m snow fell on Sunday in some localities.

In some regions rain to the high Alpine regions: These weather conditions gave rise to moistening of the snowpack also at high altitude.

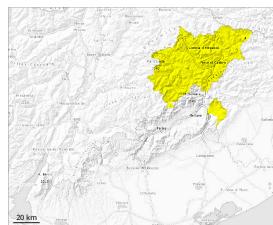

Below approximately 2200 m a little snow is lying.

Tendency

Temporary decrease in danger of moist avalanches as the temperature drops.

Danger Level 2 - Moderate

New snow

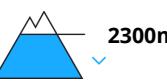

Snowpack stability: very poor

Frequency: some

Avalanche size: small

Wet snow

Snowpack stability: very poor

Frequency: few

Avalanche size: medium

Over a wide area 15 cm of snow, and up to 60 cm in some localities, will fall in the next few hours above approximately 2500 m. This snow can be released easily or naturally in all aspects above the tree line. In particular in the regions exposed to heavier precipitation many medium-sized and, in isolated cases, large avalanches are to be expected as the snowfall becomes more intense.

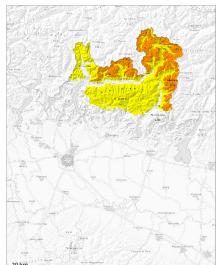

Snowpack

Over a wide area 15 cm of snow, and up to 60 cm in some localities, will fall in the next few hours above approximately 2500 m. Over a wide area new snow is lying on a weakly bonded old snowpack. Avalanches can be released in deeper layers very easily.

Danger Level 3 - Considerable

AM:

Tendency: Constant avalanche danger
on Tuesday 06 05 2025 →

New snow

Snowpack stability: **poor**
Frequency: **some**
Avalanche size: **large**

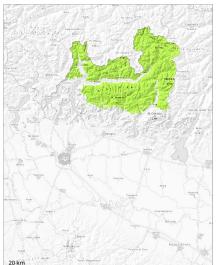

Wet snow

Snowpack stability: **poor**
Frequency: **some**
Avalanche size: **medium**

PM:

Tendency: Constant avalanche danger
on Tuesday 06 05 2025 →

New snow and wet snow represent the main danger. Medium-sized and, in isolated cases, large moist and wet avalanches are possible above approximately 2200 m.

Especially on very steep west, north and east facing slopes and above approximately 2600 m numerous medium-sized and large moist and wet avalanches are possible as a consequence of the snowfall. Wet avalanches can as before be released by a single winter sport participant.

As the day progresses as a consequence of the new snow there will be an increase in the danger of moist and wet avalanches. Individual gliding avalanches can also occur, caution is to be exercised in particular on very steep grassy slopes in the regions with a lot of snow.

Snowpack

Danger patterns

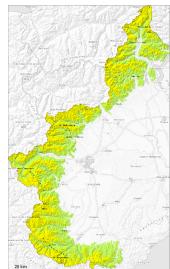

dp.10: springtime scenario

dp.6: cold, loose snow and wind

The sleet will give rise to unfavourable bonding of the snowpack. Below approximately 2200 m a little snow is lying.

Danger Level 2 - Moderate

Tendency: Constant avalanche danger →
on Tuesday 06 05 2025

Wet snow

2300m

Snowpack stability: poor

Frequency: few

Avalanche size: medium

New snow

2500m

Snowpack stability: poor

Frequency: few

Avalanche size: medium

Over a wide area snowfall above approximately 2200 m:

As a consequence of the precipitation the avalanche prone locations will become more prevalent as the day progresses. In the regions exposed to precipitation this applies in particular at high altitudes and in high Alpine regions.,

As a consequence of falling temperatures, the activity of moist and wet avalanches will decrease.

The Avalanche Warning Service currently has only a small amount of information, so that the avalanche danger should be investigated especially thoroughly in the relevant locality.

Snowpack

Danger patterns

dp.10: springtime scenario

dp.3: rain

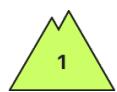

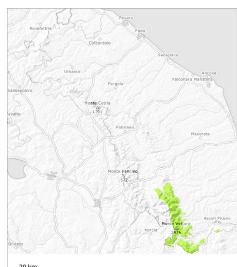

The surface of the snowpack will only just freeze.

Over a wide area new snow and wind slabs are lying on a moist old snowpack.

Below approximately 2300 m a little snow is lying.

Danger Level 1 - Low

Tendency: Constant avalanche danger
on Tuesday 06 05 2025 →

Wet snow

Snowpack stability: **very poor**

Frequency: **few**

Avalanche size: **small**

Moist and wet avalanches are the main danger.

Above approximately 2000 m mostly small natural wet avalanches are possible. The avalanche prone locations are to be found especially in gullies and bowls and on very steep slopes. The next avalanche bulletin will appear on 1 December, or sooner in the event of an unexpected change in the avalanche situation.

Snowpack

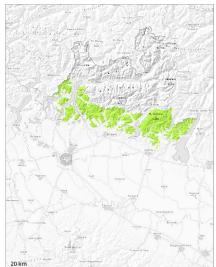

Danger patterns

dp.10: springtime scenario

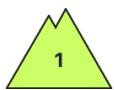

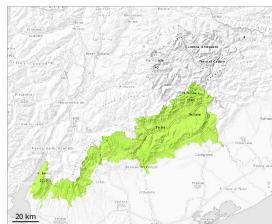

At low and intermediate altitudes no snow is lying. At elevated altitudes the snowpack is subject to significant local variations. The older wind slabs are to be found especially in gullies and bowls and in the high Alpine regions. The weather conditions gave rise to extreme and thorough wetting of the snowpack.

Danger Level 1 - Low

Danger Level 1 - Low

Snowpack stability: **very poor**

Frequency: **few**

Avalanche size: **small**

The danger of wet and gliding avalanches will increase but remain within the current danger level.

Snowpack

The rain will give rise to extreme and thorough wetting of the snowpack in all aspects below approximately 2300 m. These conditions will cause a very rapid weakening of the snowpack.
