

Avalanche danger
updated on 5.5.2026, 17:00

region A

Considerable (3-)

Wind slab

Avalanche prone locations

Danger description

As a consequence of new snow and southerly wind, avalanche prone wind slabs will form. Single winter sport participants can release avalanches, including medium-sized ones. The number and size of avalanche prone locations will increase as the day progresses. The avalanche danger will increase but remain within the current danger level. Experience in the assessment of avalanche danger is required. The Avalanche Warning Service currently has only a small amount of information that has been collected in the field, so that the avalanche danger should be investigated especially thoroughly in the relevant locality.

Moderate (2)

Wet snow

The surface of the snowpack will cool hardly at all during the overcast night. As a consequence of the precipitation wet avalanches are possible at any time. This applies in particular on steep north facing slopes between approximately 2200 and 2600 m. Mostly avalanches are medium-sized.

region B

Moderate (2=)

Wind slab

Avalanche prone locations

Danger description

The fresh wind slabs are prone to triggering. The avalanche prone locations are to be found in particular in gullies and bowls, and behind abrupt changes in the terrain. The wind slabs are to be evaluated with care and prudence in steep terrain. As the day progresses as a consequence of new snow and wind there will be an increase in the avalanche danger within the current danger level.
The Avalanche Warning Service currently has only a small amount of information that has been collected in the field, so that the avalanche danger should be investigated especially thoroughly in the relevant locality.

Moderate (2)

Wet snow

The surface of the snowpack will cool hardly at all during the overcast night. As a consequence of the precipitation wet avalanches are possible at any time. This applies in particular on steep north facing slopes between approximately 2200 and 2600 m. Mostly avalanches are medium-sized.

region C

Moderate (2-)

Wind slab

Avalanche prone locations

Danger description

As a consequence of new snow and a moderate southerly wind, small wind slabs will form at elevated altitudes. These are to be evaluated with care and prudence in very steep terrain. Apart from the danger of being buried, restraint should be exercised in particular in view of the danger of avalanches sweeping people along and giving rise to falls. The avalanche danger will increase a little during the day.
The Avalanche Warning Service currently has only a small amount of information that has been collected in the field, so that the avalanche danger should be investigated especially thoroughly in the relevant locality.

Moderate (2)

Wet snow

The surface of the snowpack will cool hardly at all during the overcast night. As a consequence of the precipitation wet avalanches are possible at any time. This applies in particular on steep north facing slopes between approximately 2200 and 2600 m. Mostly avalanches are medium-sized.

region D

Moderate (2)

Wet snow
The surface of the snowpack will cool hardly at all during the overcast night. As a consequence of the precipitation wet avalanches are possible at any time. This applies in particular on steep north facing slopes between approximately 2200 and 2600 m. Mostly avalanches are medium-sized.

Low (1)

No distinct avalanche problem

Avalanche prone locations

Danger description
Dry avalanches can in isolated cases be released in near-surface layers. This applies in particular on extremely steep north facing slopes. Mostly the avalanches are small. Apart from the danger of being buried, restraint should be exercised in particular in view of the danger of avalanches sweeping people along and giving rise to falls.
The Avalanche Warning Service currently has only a small amount of information that has been collected in the field, so that the avalanche danger should be investigated especially thoroughly in the relevant locality.

region E

Low (1)

Wet snow, Gliding snow
The surface of the snowpack will freeze very little. As a consequence of the rain individual wet and gliding avalanches are possible, in particular on steep north facing slopes. Restraint should be exercised because avalanches can sweep people along and give rise to falls.

Snowpack and weather

updated on 5.5.2026, 17:00

Snowpack

Fresh and drifted snow is prone to triggering at high altitudes, and such layers are at their thickest on the main Alpine ridge and south of there. North of the main Alpine ridge, fresh snowdrift accumulations are mostly small to medium-sized. Over the often cloudy night into Wednesday, the surface of the snowpack will barely freeze, even at high altitudes. With the further decrease in temperature, isolated wet avalanches will remain possible, especially on north-facing slopes between 2200 and 2600 m, where the snowpack is becoming wet for the first time.

Weather review for Tuesday

After a mostly cloudy night, there was hardly any sunshine during the day. On the main Alpine ridge and south of there, some snow fell above approximately 2000 m.

Fresh snow

From Sunday afternoon to Tuesday afternoon above approximately 2300 m:

- main Alpine ridge in Valais, Val Bedretto: 10 to 20 cm
- rest of Valais, main Alpine ridge from the Gotthard Pass and south of there: a few centimetres

Temperature

At midday at 2000 m, between +7 °C in the north and +1 °C in the south

Wind

Strong southerly during the night, moderate to strong during the day

Weather forecast to Wednesday

The first half of the night will continue to see some clear intervals in the east. Elsewhere there will be frequent precipitation, which will be heaviest in the south. The snowfall level will drop to around 1900 m in the west and in northern Ticino, while in the east and far south it will remain at 2200 m.

Fresh snow

From Tuesday afternoon to Wednesday afternoon, above around 2500 m:

- main Alpine ridge from the Nufenen Pass to the Bernina region and south of there: 20 to 40 cm, locally up to 50 cm
- directly adjacent to the north, northern Alpine ridge from the Trient region to the Glarus Alps and rest of main Alpine ridge in Valais: 10 to 20 cm
- other regions a widespread 5 to 10 cm

Temperature

At midday at 2000 m, between +4 °C in the northeast and +2 °C elsewhere

Wind

Moderate south to southwesterly, easing somewhat in the west during the day

Outlook to Friday

During the night into Thursday, some snow will continue to fall above approximately 1800 m, especially in the south and east. During the day, it will be cloudy with bright intervals and isolated showers. In Valais, conditions will be very sunny. On Friday, it will be cloudy with bright intervals on the southern flank of the Alps and elsewhere reasonably sunny. Winds will be mostly light southerlies on both days.

There will be hardly any change in the danger of dry avalanches on Thursday. On Friday the danger will decrease, but only slowly on steep west-, north- and east-facing slopes at high altitudes. Where there is sunshine, moist loose snow avalanches are to be expected in those regions with fresh snow. Isolated wet avalanches which sweep away the entire snowpack are possible in isolated cases, especially on north-facing slopes between 2200 and 2500 m.
